

Prakash, V. Mutants excreting lysine,
histidine and methionine in *N. crassa*.

Many of the protein amino acid analogues or antimetabolites, being growth inhibitory, have been reported as toxic. Mutant strains resistant to the amino acid analogues L-thiosine (S- β -aminoethyl-L-cysteine), DL-2 thiazolalanine and L-ethionine have been isolated. These mutants overproduce and accumulate, respectively, lysine, histidine and methionine in the culture medium.

A conidial suspension in liquid minimal medium at pH 7.8 containing 1×10^7 conidia/ml (conidia harvested from 72 hour-old sensitive Malayan wild-type strain UM-29) was treated with 2.8 mg/ml N-methyl- N'-nitro-N-nitrosoguanidine for four hours at 25°C. After the mutagenic treatment, the conidia were immediately plated on sorbose minimal agar medium at 37°C containing the appropriate amino acid analogue (0.5 mg/ml L-thiosine, 0.5 mg/ml DL-2 thiazolalanine or 0.5 mg/ml L-ethionine) and incubated at 25°C for 48-72 hours to isolate mutants resistant to the analogues. It has been possible to isolate a large number of such mutants.

Table 1 presents the amino acid analogue resistant mutants in which no significantly detectable difference in growth rates or mycelial weights from the sensitive parent wild-type UM-29 was observed as long as other nutrient limitations were not imposed. Each of the three categories of mutants was found to be sensitive to the toxic effect of the other amino acid analogues.

Table 1. Growth of wild-type and resistant strains on amino acid analogues*.

* The figures are averages of two independent experiments and are expressed as mycelial dry wt in mg from 96-hour cultures grown in 20 ml minimal medium at 28°C. ** Concentration in mg/ml. - = no growth.

and me-3(36104); me-P(C124) and me-7(39103); me-8(P53) and me-5(9666); me-6(35809), whereas they did not feed the lysine-, quiring or histidine-requiring indicator strains.

The excretion of amino acids into the medium by these mutants is indicative of control deficiencies resulting in impaired regulation of biosynthesis. Since such mutants differ from the wild type only in analogue-resistance and the excretion of the individual amino acids, the mutations producing these effects must be specific for the amino acid over-production and excretion without leading to a general breakdown in the cells.

Division of Genetics, School of Biological Sciences, University of Malaya, Kuala Lumpur, Malaysia.

Auxanographic feeding tests indicated over-production of specific amino acids and their secretion into the liquid culture medium. A partition tube apparatus consisting of two tubular sections separated by a Gelman metrical membrane filter (Grade GA-8, 0.2 μ porosity) was used. The porosity of the membrane was such that it allowed free flow of the liquid culture medium without hyphae or conidia passing from one section to the other. 30 ml of liquid minimal medium was charged in each of the tubular sections and autoclaved. An "excretor mutant" was inoculated in one section and 72 hours later the "double auxotroph indicator strain" was inoculated in the other.

The mutants isolated all proved to be heavy feeders across the membrane, as they supported full growth of the corresponding indicator strain. The four thiorine-resistant mutants supported the growth of the lysine-requiring double auxotrophic strains lys-1(33933); lys-3(28815) and lys-2(37101); lys-5(D56 85), but did not feed the histidine- or methionine-requiring indicator strains. The seven thiazoolanine-resistant strains supported the growth of the three histidine-requiring strains his-1(C85); his-3(K446) and his-4(C141); his-7(K227) and his-2(C94); his-5(K52). They did not feed the lysine- or methionine-requiring indicator strains. All five of the ethionine-resistant strains supported the growth of the four double auxotrophic methionine-requiring strains me-1(38706); me-10(PD' and me-3(36104); me-P(C124) and me-7(39103); me-8(P53) and me-5(9666); me-6(35809), whereas they did not feed the lysine-, quiring or histidine-requiring indicator strains.
